Abstract: Iris Recognition is one of the most biometric identification systems that identify people based on their iris. In this paper the iris recognition system is implemented by using Hough Transform and Canny edge detection techniques. In this paper the iris recognition via many steps, these steps are image acquisition, edge detection, localization, feature extraction, and matching. Two types of extractions: eight sub-images and sixteen sub-images are used to divide the iris images. The implemented system uses CASIA iris database. This paper provides an efficient iris identification system and the software to perform this research developed using the Matlab programming language.

Keywords: Iris Recognition, Cannny, Localization, Feature Extraction, CASIA

1. INTRODUCTION
Iris recognition is a reliable biometric system that can be used to identify a person by analysing the patterns found in the iris. Various methods have been intended by different researchers. But this system described accurate iris preprocessing using canny edge detection, efficient extraction of features in an eye image and generate iris feature vector from iris sub-images after feature extraction. First, the system acquires, through a video camera, a digitized image of an eye of the human to be identified. But the system applies the CASIA iris image database to classify iris features and pupil detection. The original image needs to be preprocessed. After edge detection, iris features are extracted with statistical based feature extraction method. This method based on angular orientation form and it divides the 8 potions and 18 portions. It is successfully applied as feature extractors for feature extraction stage in practical test. After applying this method on an original image, a set of sub-images is obtained at different resolution levels. The mean and dispersion of each sub-image are extracted as texture features. Finally, mean square distance is used to perform the identification stage, iris matching, and this new method achieves much higher identification rate.

The iris is highly protected, non-invasive and ideal for handling applications requiring management of large user groups, like voter ID management. The iris recognition techniques potentially prevent unauthorized access to ATM, cellular phone, desktop PCs, workstations, buildings and computer networks. The accuracy of iris recognition systems is proven to be much higher compared to other types of biometric systems like fingerprint, handprint and voiceprint. Since biometric authentication is a very up to date technique being used for security and identification purposes, plenty of work is done on it. Tieniu Tan and Zhenan Sun has proposed that the iris acknowledgment calculation taking into account PCA (Principal Component Analysis) is initially presented and after that, iris picture combination technique is displayed. Kefeng Fan has proposed a productive procedure on iris limitation, and quality appraisal. Eje Wi Liam proposed a system consisting of two parts: Localizing Iris and Iris Pattern Recognition. They used digital camera for capturing images; from that captured images, iris is extracted. V Saishanmuga Raja, proposed a method for personal recognition based on iris recognition using Genetic algorithm and Neural Network. The process of iris recognition consists of localization of the iris region and age group of data set of iris images followed by iris pattern acknowledgement. Dr. Eka Walia has worked on comparing the different biometric techniques and has given the clear view of accuracy received each by one of them. Zhaofeng He, Tieniu Tan has given a detailed study on segmentation of image which extracts the required features.

2. IRIS RECOGNITION SYSTEM

![Figure 1: System Design for Iris Identification System](image)

2.1 Image Acquisition
Image acquisition is the main critical in iris recognition system. For image acquisition, the iris image must have an
average diameter of 12mm and the camera used should have enough resolution to capture the details of the iris pattern. The proposed system uses CASIA iris database. CASIA iris database image uses a special camera that operates in the infrared spectrum of light, not visible by the human eye. This paper is based on the CASIA image database. Images are 320x320 pixels grayscale taken by a digital optical sensor designed by NLPR (National Laboratory of Pattern Recognition) of Chinese Academy of Sciences. There are 108 classes or iris in a total of 756 iris images.

2.2 Image Pre-processing

2.2.1 Edge Detection

Edge detection is used for the edges in an eye image. It consists of three major steps. The proposed system uses canny edge detection algorithm. The Canny edge detection algorithm is widely known as the optimal edge detector. The first and most apparent is low error rate. It is important that edges occurring in images should not be missed and that there be no responses to non-edges. The second criterion is that the edge points will be well localized. In other words, the distance between the edge pixels as found by the detector and the actual edge is to be at a minimum. A third criterion is to have only one response to a single edge. This was applied because the first two were not substantial enough to completely eliminate the possibility of multiple responses to an edge.

It is a multi-step detector which performs smoothing and filtering, non-maxima suppression, followed by a connected-component analysis stage to detect “true” edges, while suppressing “false” non-edge filter responses.

2.2.2 Localization

Iris localization is very important for an iris recognition system and it is crucial for the performance of that system. Hough circle transformation method in the font named Times. Right margins should be this research aims to find the parameters, centers and radii, of the two iris boundaries, detecting the lower and upper eyelid and isolating eyelashes. Localizing the iris outer boundary, an approach based on boundary point detection and curve fitting is adopted. First, a set of radial boundary points is detected by performing the image integral projection along angular directions within specified image blocks.

2.3 Feature Extraction

Feature extraction is the most important stage in the iris recognition system. The success or failure of identification system highly depends on the utility of the information that the feature extraction stage provides. Feature extraction involves selecting the significant features from an input pattern, and transforming them through some function that can provide some informative measurements for the input pattern. There are many different methods in feature extraction. Various methods have been proposed by different researchers. Important features are extracted from an eye image.

3. COMPARISON OF FEATURE EXTRACTIONS

Eighteen sub-images and eight sub-images values were calculated for the comparison of the eye image.

www.ijsea.com
If \( d_i \) measurements of \( I \) known samples of feature vectors and \( X \) samples of each, then \( N \) features space that contains the \( I \times X \) points according to the Equation. If the point is selected, in the feature space, which is closest to the current sample, then it is selected the sample’s nearest neighbor.

4. CLASSIFICATION
For the comparison of the two iris images, mean square distance measure method is used. Mean square distance is one of the techniques that measures the distance with eye vector. It defines as:

\[
d_i = \sum_{k=1}^{N} (I_k - X_{ik})^2
\]

5. CONCLUSION
This paper has proposed on iris identification system, which has been tested using different types of feature extraction. The purpose approach drives data from CASIA database and iris recognition system shows that the approach is secure and privacy-preserving. The system also shows the experimental results on iris. Experimental results show that the proposed approach has good recognition performance and speed. In the feature, it would be necessary to experiment on a larger iris database in various environments to make the system more reliable.

6. ACKNOWLEDGMENTS
The author wishes to express her deep gratitude to Dr. Theingi, Rector, Technological University (Thanlyin), for her encouragement and invaluable permission for carrying out the research work. The author is deeply grateful to her chairman, Dr. Ei Ei Myat, Professor and Head, Department of Information Technology, Technological University (Thanlyin), for her idea, patience, kindness and suggestion. The author would like to express a greatful thank to her supervisor, Daw Aye Kyi Pyar Shwe, Lecturer, Department of Information Technology, Technological University (Thanlyin), for her close supervision, kind guidance, valuable suggestions, understanding and generous encouragements during a long period of study. The author is also thankful to all teachers for their guidance. Finally, The author is especially grateful to her parents for their support and continuous encouragement to complete and succeed this paper.
